# The Stigler-Luckock model for the evolution of an order book

#### Jan M. Swart joint with Marco Formentin, Jana Plačková

Bochum, March 2nd, 2016.

回 と く ヨ と く ヨ と

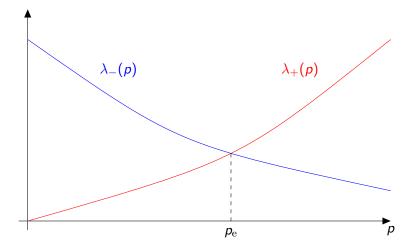

In classical economic theory (Walras,<sup>1</sup> 1874), the *price* of a commodity is determined by *demand* and *supply*.

Let  $\lambda_{-}(p)$  (resp.  $\lambda_{+}(p)$ ) be the total *demand* (resp. *supply*) for a commodity at price level p, i.e., the total amount that people are willing to buy (resp. sell), per unit of time, for a price of at most (resp. at least) p per unit.

<sup>1</sup>Walras developed the theory of equilibrium markets in his book *Éléments* d' économie politique pure.

Jan M. Swart joint with Marco Formentin, Jana Plačková The Stigler-Luckock model for the evolution of an order book

#### Some classical ecomomic theory

**Postulate** In an equilibrium market, the commodity is traded at the *equilibrium prize*  $p_e$ .

Jan M. Swart joint with Marco Formentin, Jana Plačková

The Stigler-Luckock model for the evolution of an order book

On stock & commodity exchanges, goods are traded using an *order book*.

The order book for a given asset contains a list of offers to buy or sell a given amount for a given price. Traders arriving at the market have two options.

Place a market order, i.e., either buy (buy market order) or sell (sell market order) n units of the asset at the best price available in the order book.

On stock & commodity exchanges, goods are traded using an *order book*.

The order book for a given asset contains a list of offers to buy or sell a given amount for a given price. Traders arriving at the market have two options.

- Place a market order, i.e., either buy (buy market order) or sell (sell market order) n units of the asset at the best price available in the order book.
- Place a limit order, i.e., write down in the order book the offer to either buy (buy limit order) or sell (sell limit order) n units of the asset at a given price p.

(ロ) (同) (E) (E) (E)

On stock & commodity exchanges, goods are traded using an *order book*.

The order book for a given asset contains a list of offers to buy or sell a given amount for a given price. Traders arriving at the market have two options.

- Place a market order, i.e., either buy (buy market order) or sell (sell market order) n units of the asset at the best price available in the order book.
- Place a limit order, i.e., write down in the order book the offer to either buy (buy limit order) or sell (sell limit order) n units of the asset at a given price p.

Market orders are matched to existing limit orders according to a mechanism that depends on the trading system.

Luckock (2003) (& again Plačková (2011)) (re-) reinvented the following model.

► Traders arrive at the market at times of a Poisson process.

・ 同 ト ・ ヨ ト ・ ヨ ト

Luckock (2003) (& again Plačková (2011)) (re-) reinvented the following model.

- Traders arrive at the market at times of a Poisson process.
- Each trader either wants to buy or sell exactly one item of the asset.

・ 同 ト ・ ヨ ト ・ ヨ ト

Luckock (2003) (& again Plačková (2011)) (re-) reinvented the following model.

- Traders arrive at the market at times of a Poisson process.
- Each trader either wants to buy or sell exactly one item of the asset.
- ► Each trader has a *maximal buy price* or *minimal sell price*.

・ 同 ト ・ ヨ ト ・ ヨ ト …

Luckock (2003) (& again Plačková (2011)) (re-) reinvented the following model.

- Traders arrive at the market at times of a Poisson process.
- Each trader either wants to buy or sell exactly one item of the asset.
- ► Each trader has a *maximal buy price* or *minimal sell price*.
- ► Traders who want to buy (sell) for at most (least) p arrive with Poisson intensity μ<sub>−</sub> = −dλ<sub>−</sub> (μ<sub>+</sub> = dλ<sub>+</sub>).

Luckock (2003) (& again Plačková (2011)) (re-) reinvented the following model.

# Stigler's model

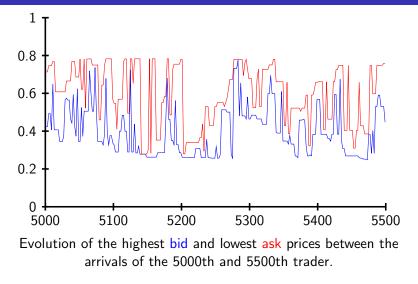

F10. 1.-Hypothetical sequence of transaction prices, generated by sequence of random numbers, and maximum unfulfilled bid and minimum unfulfilled ask prices (equilibrium price of 29% or 30).

Stigler (1964) already simulated the same model with  $\mu_{\pm}$  the uniform distributions on a set of 10 possible prices.

The theoretical equilibrium price  $p_{\rm e} = 0.5$  is never attained.

There are magic numbers  $q_{\min} \approx 0.2177(2)$  and  $q_{\max} = 1 - q_{\min}$  such that eventually:

- ▶ Buy limit orders at a price below *q*<sub>min</sub> are never matched with a market order.
- Sell limit orders at a price above  $q_{\text{max}}$  are never matched.
- ► The bid and ask prices keep fluctuating between q<sub>min</sub> and q<sub>max</sub>.

The theoretical equilibrium price  $p_{\rm e}=0.5$  is never attained.

There are magic numbers  $q_{\min} \approx 0.2177(2)$  and  $q_{\max} = 1 - q_{\min}$  such that eventually:

- ▶ Buy limit orders at a price below *q*<sub>min</sub> are never matched with a market order.
- Sell limit orders at a price above  $q_{\text{max}}$  are never matched.
- ► The bid and ask prices keep fluctuating between q<sub>min</sub> and q<sub>max</sub>.
- The spread is huge, most of the time.

Luckock has a **formula** for  $q_{\min}$  and  $q_{\max}$ .

In particular, for the model on [0,1] with  $\lambda_{-}(x) = 1 - x$  and  $\lambda_{+}(x) = x$ , Luckcock claims:  $q_{\min} := 1 + 1/z$  with z the unique solution of the equation  $1 + z + e^{z} = 0$ .

Numerically,  $q_{\min} \approx 0.21781170571980$ .

Luckock proves his claim based on the following assumptions:

- The model is stationary.
- ► There exist 0 < q<sub>min</sub> < q<sub>max</sub> < 1 such that buy (sell) limit orders below q<sub>min</sub> (above q<sub>max</sub>) are never matched.
- ► All buy (sell) limit orders above q<sub>min</sub> (below q<sub>max</sub>) are eventually matched.

(ロ) (同) (目) (日) (日) (の)

Let  $\overline{I} = [I_-, I_+]$  be the interval of possible prices. We assume that  $\lambda_{\pm} : \overline{I} \to [0, \infty)$  are continuous,  $\lambda_-$  is nonincreasing, and  $\lambda_+$  nondecreasing.

We drop the assumption that  $\lambda_{-}(I_{+}) = 0 = \lambda_{+}(I_{-})$ .

Instead, with rate  $\lambda_{-}(I_{+})$  (resp.  $\lambda_{+}(I_{-})$ ), a trader arrives that places a buy market order (resp. sell market order) if the order book contains at least one sell limit order (resp. buy limit order), and does nothing else.

The advantage of allowing  $\lambda_{-}(I_{+}), \lambda_{+}(I_{-}) > 0$  is that the process can be positive recurrent.

## Luckock's equation

**[Luckock '03]** Let  $M^{\pm}$  denote the price of the best buy/sell offer. Assume that the process is in equilibrium. Then

$$f_{-}(x) := \mathbb{P}[M^{-} < x]$$
 and  $f_{+}(x) := \mathbb{P}[M^{+} > x]$ 

solve the differential equation

(i) 
$$f_-d\lambda_+ = -\lambda_-df_+$$
,  
(ii)  $f_+d\lambda_- = -\lambda_+df_-$   
(iii)  $f_+(I_-) = 1 = f_-(I_+)$ .

**Proof:** Since buy orders are added to  $A \subset (q_{\min}, q_{\max})$  at the same rate as they are removed

$$\int_{\mathcal{A}} \mathbb{P}[M^{-} < x] \, \mathrm{d}\lambda_{+}(\mathrm{d}x) = \int_{\mathcal{A}} \lambda_{-}(x) \, \mathbb{P}[M^{+} \in \mathrm{d}x].$$

**Theorem** Assume  $\lambda_{-}(I_{+}), \lambda_{+}(I_{-}) > 0$ . Then Luckock's equation has a unique solution.

**Conjecture** A Stigler-Luckock model is positive recurrent if and only if the unique solution to Luckock's equation satisfies  $f_{-}(I_{+}) > 0$  and  $f_{+}(I_{-}) > 0$ .

I have a proof under the "asymmetry" assumption that  $\lambda_{-}(I_{+}) \neq \lambda_{+}(I_{-})$ .

With new methods, I am hopeful to prove the full conjecture soon.

▲□▶ ▲□▶ ▲目▶ ▲目▶ = ● ● ●

# Weight functions

Let  $\mathcal{X}_t^{\pm}$  denote the sets of buy and sell limit orders in the order book at time t and consider a weighted sum over the limit orders of the form

$$W_t := \sum_{x \in X_t^-} w_-(x) + \sum_{x \in X_t^+} w_+(x),$$

where  $w_{\pm}:\overline{I}\to\mathbb{R}$  are "weight" functions. Lemma One has

$$\frac{\partial}{\partial t}\mathbb{E}[W_t] = q_-(M_t^-) + q_+(M_t^+),$$

where  $q_-:[I_-,I_+) o \mathbb{R}$  and  $q_+:(I_+,I_-] o \mathbb{R}$  are given by

$$q_{-}(x) := \int_{x}^{I_{+}} w_{+} d\lambda_{+} - w_{-}(x)\lambda_{+}(x) \qquad (x \in [I_{-}, I_{+})),$$
  
$$q_{+}(x) := -\int_{I_{-}}^{x} w_{-} d\lambda_{-} - w_{+}(x)\lambda_{-}(x) \qquad (x \in (I_{-}, I_{+}]).$$

Jan M. Swart joint with Marco Formentin, Jana Plačková

The Stigler-Luckock model for the evolution of an order book

- 4月 1 4 日 1 4 日 1 日 日

**Theorem** For each  $z \in \overline{I}$ , there exist a unique pair of weight functions  $(w_-, w_+)$  such that

$$\frac{\partial}{\partial t}\mathbb{E}[W_t] = \mathbb{1}_{\left\{\boldsymbol{M}_t^- \leq z\right\}} - f_-(z),$$

where  $(f_-, f_+)$  is the unique solution to Luckock's equation. Likewise, there exist a unique pair of weight functions  $(w_-, w_+)$  such that

$$\frac{\partial}{\partial t}\mathbb{E}[W_t] = \mathbb{1}_{\{M_t^+ \ge z\}} - f_+(z).$$

This gives an interpretation to Luckock's equation even when its solutions take negative values, Moreover, the theorem is useful even in non-stationary settings.

- Gabrielli and Caldarelli's (2007,2009) modification of Barabási's queueing model (2005).
- Two toy models for canyon formation.
- ► The modified Bak-Sneppen model (Meester & Sarkar, 2012).

All these models contain a rule "kill the largest (smallest) particle" and (seem to) exhibit *self-organized criticality*.

The profile after 10,000 steps.

We find the same critical point  $q_{\min}$  as for the Stigler-Luckock model.

In fact, the models are very similar:

- ► In the Stigler-Luckock model, interpret a buy limit order as an increment -1 and interpret a sell limit order as an increment +1.
- Assume that each trader places both a buy and sell limit order, at the (almost) same price, but with the sell order infinitesimally on the right of the buy order.

Then we obtain the canyon model.

A river flows on the left.

The process just described defines a Markov chain  $(X_k)_{k\geq 0}$  where  $X_k \subset [0,1]$  is a finite set.

**Consistency:** For each 0 < q < 1, we observe that the *restricted process* 

 $(X_k \cap [0,q])_{k \ge 0}$ 

is a Markov chain.

**Theorem 1** The restricted process is positively recurrent for  $q < 1 - e^{-1}$  and transient for  $q > 1 - e^{-1}$ .

**Theorem 2** The restricted process is null recurrent at  $q = 1 - e^{-1}$ .

# A weight function

#### Proof of Theorems 1 and 2

For t > 0, consider the weighted sum over points in  $X_k$ 

$$W_k^{(t)} := \sum_{x \in X_k} e^x \mathbb{1}_{[0,t]}(x).$$

Then

$$\mathbb{E}[W_{k+1}^{(t)} - W_k^{(t)} \mid \min(X_k) = m] = t - \mathbb{1}_{[0,t]}(m).$$

In particular, the process  $W^{(t)}$  stopped at the first time that  $\min(X_k) > t$  is

- A supermartingale for t < 1,
- A martingale for t = 1,
- A submartingale for t > 1.

Someone receives emails according to a Poisson process with intensity  $\lambda_{\rm in}$  and answers emails at times of a Poisson process with intensity  $\lambda_{\rm out}.$ 

Realistically,  $\lambda_{in} > \lambda_{out}$ .

The recipent assigns a *priority* to each incoming email, and always answers the email with the highest priority in the inbox (or does nothing if the inbox is empty).

Priorities are i.i.d. with some atomless law. Without loss of generality we can take the uniform distribution on  $[-\lambda_{in}, 0]$ .

Easy to prove: In the long run, emails with priorities below  $-\lambda_{\rm out}$  are never answered, while all emails with a priority above  $-\lambda_{\rm out}$  are eventually answered.

(4月) (3日) (3日) 日

Easy to prove: In the long run, emails with priorities below  $-\lambda_{out}$  are never answered, while all emails with a priority above  $-\lambda_{out}$  are eventually answered.

**Proof:** the number of emails in the inbox with priority in  $[-\lambda, 0]$  is a random walk that jumps  $k \mapsto k + 1$  with rate  $\lambda$  and  $k \mapsto k - 1$  with rate  $\lambda_{out} 1_{\{k>0\}}$ .

(本部) (本語) (本語) (語)

Easy to prove: In the long run, emails with priorities below  $-\lambda_{out}$  are never answered, while all emails with a priority above  $-\lambda_{out}$  are eventually answered.

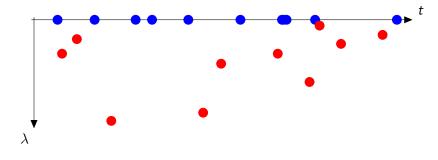

**Proof:** the number of emails in the inbox with priority in  $[-\lambda, 0]$  is a random walk that jumps  $k \mapsto k + 1$  with rate  $\lambda$  and  $k \mapsto k - 1$  with rate  $\lambda_{out} 1_{\{k>0\}}$ .

This random walk is positive recurrent for  $\lambda < \lambda_{out}$ , null recurrent for  $\lambda = \lambda_{out}$ , and transient for  $\lambda > \lambda_{out}$ .

Let  $F_{\lambda}(t)$  denote the number of emails with priority in  $[-\lambda, 0]$  that are in the inbox at time t.

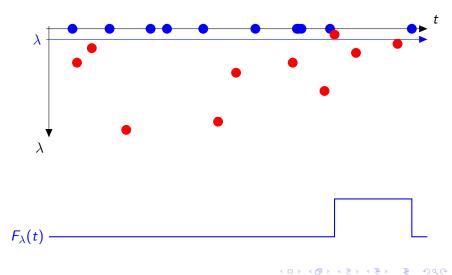

We can read off  $F_{\lambda}(t)$  from the Poisson processes describing the arrivals of new emails and answering times.

Physical systems with second order phase transitions exhibit *critical behavior* at the point of the phase transition, which is characterized by:

- Scale invariance.
- Power law decay of quantities.
- Critical exponents.

Usually, critical behavior is only observed when the parameter(s) of the system, such as the temperature, have just the right value so that we are at the point of the phase transition, also called (in this context) the *critical point*.

・ 同 ト ・ ヨ ト ・ ヨ ト …

Some physical systems show critical behavior even without the necessity to tune a parameter to exactly the right value.

In particular, this happens for systems whose dynamics find the critical point themselves. Such systems are said to exhibit *self-organized criticality*.

A classical example are sandpiles, which automatically find the maximal slope that is still stable. Adding a single grain to such a sandpile causes an avalanche whose size has a power-law distribution.

The Bak Sneppen model is another classical example of self-organized criticality and a cornerstone of Bak's (1996) book.

・同下 ・ヨト ・ヨト

In the email model, the distribution of serving times (of answered emails) has a power-law tail. Indeed, it seems that in equilibrium, at any time, the probability that the last email we have answered had spent a time  $\geq t$  in our inbox decays as  $t^{-1/2}$ .

This is quite different from the usual exponential tails in queueing theory.

This sort of power law decay, with the exponent 1/2, has even been observed in real data, provided time is measured in units proportional to the activity of the owner of the inbox (as judged from the number of emails sent). [Formentin, Lovison, Maritan, Zanzotto, J. Stat. Mech. 2015].

イロト イボト イヨト イヨト 二日

Introduced by Bak & Sneppen (1993).

Consider an ecosystem with N species. Each species has a fitness in [0, 1].

In each step, the species  $i \in \{1, ..., N\}$  with the lowest fitness dies out, together with its neighbors i - 1 and i + 1 (with periodic b.c.), and all three are replaced by species with new, i.i.d. uniformly distributed fitnesses.

There is a critical fitness  $f_c \approx 0.6672(2)$  such that when N is large, after sufficiently many steps, the fitnesses are approximately uniformly distributed on  $(f_c, 1]$  with only a few smaller fitnesses. Moreover, for each  $\varepsilon > 0$ , the lowest fitness spends a positive fraction of time above  $f_c - \varepsilon$ , uniformly as  $N \to \infty$ .

Introduced by Meester & Sarkar (2012).

Instead of the neighbors of the least fit species, choose one arbitrary other species from the population that dies together with the least fit species.

Critical point exactly  $f_c = 1/2$ .

Critical behavior at  $f_c$ : intervals between times when all individuals have a fitness >  $f_c$  have a power-law distribution with  $\mathbb{P}[\tau \ge k] \sim k^{-1/2}$ .

Proof based on coupling to a branching process.
