向下 イヨト イヨト

Assume that $\varphi : \{0,1\}^{\mathbb{Z}^d} \to \{0,1\}$ is monotone and depends on finitely many coordinates. Example: the North East Center majority rule on \mathbb{Z}^2 :

$$\varphi^{\text{NEC}}(x) := \left\{ egin{array}{ll} 1 & ext{if } x(0,0) + x(0,1) + x(1,0) \geq 2, \\ 0 & ext{if } x(0,0) + x(0,1) + x(1,0) \leq 1. \end{array}
ight.$$

We are interested in the cellular automaton $(X_n)_{n\geq 0}$ that evolves

 $X_{n+1}(i) = \begin{cases} \varphi((X_n(i+j))_{j \in \mathbb{Z}^d}) & \text{with probability } 1-p, \\ 0 & \text{with probability } p, \end{cases}$

independently for all $n \ge 0$ and $i \in \mathbb{Z}^d$.

Jan M. Swart (Czech Academy of Sciences) Peierls bounds from Toom contours

Def φ is an *eroder* if for the unperturbed cellular automaton, any finite collection of zeros disappears in finite time.

Toom's stability theorem (1980) If φ is an eroder, then $\rho(p) \rightarrow 1$ as $p \rightarrow 0$. If φ is not an eroder, then $\rho(p) = 0$ for all p > 0.

・ 同 ト ・ ヨ ト ・ ヨ ト …

Each monotone map $\varphi: \{0,1\}^{\mathbb{Z}^d} \to \{0,1\}$ can uniquely be written as

$$\varphi(x) = \bigvee_{A \in \mathcal{A}(\varphi)} \bigwedge_{i \in A} x(i),$$

 $A \in \mathcal{A}(\varphi)$ is a *minimal collection of ones* needed for $\varphi(x) = 1$. **Theorem** (Toom 1980, Ponselet 2013) φ is an eroder if and only if

$$\bigcap_{A\in\mathcal{A}(\varphi)}\operatorname{Conv}(A)=\emptyset$$

where Conv(A) is the convex hull of A. By *Helly's theorem* w.l.o.g. $|\mathcal{A}(\varphi)| \leq d + 1$.

Def A polar function is a linear function

$$\mathbb{R}^d
i z \mapsto ig(L_1(z), \dots, L_\sigma(z)ig) \in \mathbb{R}^d$$

such that
$$\sum_{s=1}^{\sigma} L_s(z) = 0$$
 $(z \in \mathbb{R}^d)$.
For $x \in \{0,1\}^{\mathbb{Z}^d}$, let $\ell_s(x) := \sup_{i \in \mathbb{Z}^d: x(i)=0} L_s(i)$.

Then for the unperturbed cellular automaton:

$$\ell_s(X_n) \leq \ell_s(X_0) - \delta_s n$$
 with $\delta_s := \sup_{A \in \mathcal{A}(\varphi)} \inf_{i \in A} L_s(i).$

The constants δ_s $(1 \le s \le \sigma)$ are *edge speeds*.

• • = • • = •

<ロ> (四) (四) (三) (三) (三)

Lemma (Toom 1980, Ponselet 2013) φ is an eroder if and only if there exists a polar function *L* such that

$$\delta := \sum_{s=1}^{\sigma} \delta_s > 0 \quad \text{with} \quad \delta_s := \sup_{A \in \mathcal{A}(\varphi)} \inf_{i \in A} L_s(i).$$

Proof of sufficiency Define the *extent* of *x* by

$$\operatorname{ext}(x) := \sum_{s=1}^{\sigma} \ell_s(x) \quad \text{with} \quad \ell_s(x) := \sup_{i \in \mathbb{Z}^d: \ x(i)=0} L_s(i).$$

Then $ext(x) \ge 0$ if there is at least one zero since $\sum_{s=1} L_s(z) = 0$. Moreover $ext(X_n) \le ext(X_0) - \delta n$.

Let $\Phi = (\Phi_{(i,t)})_{(i,t) \in \mathbb{Z}^d \times \mathbb{Z}}$ be an i.i.d. collection of maps with

$$\mathbb{P}ig[\Phi_{(i,t)}=arphi^0ig]= p \hspace{1mm} ext{and} \hspace{1mm} \mathbb{P}ig[\Phi_{(i,t)}=arphiig]=1-p,$$

where $\varphi^0(x) := 0$ denotes the *trivial zero map*. A *trajectory* of Φ is a function $(i, t) \mapsto x_t(i)$ such that

$$x_t(i) = \Phi_{(i,t)}\big((x_{t-1}(i+j))_{j\in\mathbb{Z}^d}\big) \qquad \forall (i,t).$$

Lemma There a.s. exists a *maximal* trajectory \overline{X} . **Aim** For small p, derive lower bound on $\rho(p) := \mathbb{P}[\overline{X}_0(0) = 1]$.

Def A *Toom graph* is a directed graph with edges of σ different *charges* and three types of vertices:

- At a *source*, σ directed edges emerge, one of each charge.
- At a *sink*, σ directed edges converge, one of each charge.
- At an *internal vertex*, there is one incoming edge and one outgoing edge, and they are of the same charge.

In addition, there can be *isolated vertices* which we can think of as a source and sink at the same time.

・ 同 ト ・ ヨ ト ・ ヨ ト

Toom contours

A Toom graph with three charges.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ →

Main idea A *Toom contour* is a connected Toom graph embedded in the plain, with one special source called the *root*.

If $\overline{X}_0(0) = 0$, then there exists a Toom contour T rooted at (0,0) such that the sinks of T correspond to *defective* space-time points, where the trivial map φ^0 is applied. Then:

$$\mathbb{P}\big[\overline{X}_0(0)=0\big] \leq \sum_{\mathcal{T}} \mathbb{P}\big[\mathcal{T} \text{ is present in } \Phi\big] \leq \sum_{\mathcal{T}} p^{n_{\mathrm{sink}}(\mathcal{T})}.$$

This tends to zero as $p \rightarrow 0$ provided

$$N_n^{\rm sink} := \#\{T : n_{\rm sink}(T) = n\}$$

・ 同 ト ・ ヨ ト ・ ヨ ト

grows at most exponentially in n.

It is not hard to show that there exists a $R < \infty$ such that

$$N_n^{\text{edge}} \leq R^n$$
 with $N_n^{\text{edge}} := \#\{T : n_{\text{edge}}(T) = n\}.$

Need to show that $n_{\mathrm{sink}}(T) \geq cn_{\mathrm{edge}}(T)$ for some c > 0.

Idea: edges with charge s move in the direction where L_s increases, *except* for edges coming out of sources. As a result:

$$n_{\mathrm{sink}}(T) = n_{\mathrm{source}}(T) \ge cn_{\mathrm{edge}}(T)$$

for some c > 0.

Def An *embedding* of a Toom graph with vertex set V is a map

$$V \ni \mathbf{v} \mapsto (\psi(\mathbf{v}), h(\mathbf{v})) \in \mathbb{Z}^d imes \mathbb{Z}$$

- The height (=negative time) h increases by 1 along each directed edge.
- Sinks do not overlap with any other vertices.
- Internal vertices of the same charge do not overlap.

A *Toom contour* is an embedded connected Toom graph with one special source, the *root*, whose height is minimal among all vertices.

向下 イヨト イヨト

Let φ be an eroder. For each $1 \leq s \leq \sigma$, choose $A_s(\varphi) \in \mathcal{A}(\varphi)$ such that

$$\delta_{s} := \sup_{A \in \mathcal{A}(\varphi)} \inf_{i \in A} L_{s}(i) = \inf_{i \in A_{s}(\varphi)} L_{s}(i).$$

Def A Toom contour is *present* in $\Phi = (\Phi_{(i,t)})_{(i,t) \in \mathbb{Z}^d \times \mathbb{Z}}$ if:

- Sinks correspond to vertices where the trivial map φ⁰ is applied.
- If (v, w) is a directed edge of charge s coming out of an internal vertex or the root, then ψ(w) − ψ(v) ∈ A_s(φ).
- For directed edges emerging at other sources $\psi(w) \psi(v) \in \bigcup_{s=1}^{\sigma} A_s(\varphi).$

Theorem If $\overline{X}_0(0) = 0$, then there is a Toom contour rooted at (0,0) present in Φ .

Toom contours

A Toom contour for the *cooperative branching map* $\varphi^{\text{coop}}(x) := x(0,0) \lor (x(0,1) \land x(1,0)).$

Toom contours

 $L_2(z_1, z_2) = z_1 + z_2$, and $L_1(z_1, z_2) = -z_1 - z_2$.

◆□ > ◆□ > ◆臣 > ◆臣 > ─ 臣 ─ のへで

The Peierls argument

Lemma There exists a c > 0 such that $n_{sink} \ge cn_{edge} + 1$.

Proof

$$\sum_{s=1}^{\sigma} \sum_{(v,w)\in E_s} \left(L_s(\psi(w)) - L_s(\psi(v)) \right)$$

$$= \sum_{v\in V} \sum_{s=1}^{\sigma} \left\{ \sum_{u: (u,v)\in E_s} L_s(\psi(v)) - \sum_{w: (v,w)\in E_s} L_s(\psi(v)) \right\} = 0.$$

Let E_s° denote the edges of charge *s* out of a source different from the root and E_s^* the other edges. Then

$$0 = \sum_{s=1}^{\sigma} \sum_{(v,w)\in E_s^*} \underbrace{\left(L_s(\psi(w)) - L_s(\psi(v))\right)}_{\geq \delta_s} + \sum_{s=1}^{\sigma} \sum_{(v,w)\in E_s^\circ} \underbrace{\left(L_s(\psi(w)) - L_s(\psi(v))\right)}_{\geq -\kappa}.$$

・ 同 ト ・ ヨ ト ・ ヨ ト

Lemma The number of Toom contours rooted at (0,0) with N edges is bounded by R^n for some $R < \infty$.

Let \mathcal{T}_0 denote the set of all Toom contours rooted at (0,0). Let $n_{\text{sink}}(T)$ denote the number of sinks of T. Let N_n^{edge} denote the number of $T \in \mathcal{T}_0$ with n edges. Then

$$\mathbb{P}[\overline{X}_0(0) = 0] \leq \sum_{T \in \mathcal{T}_0} \mathbb{P}[T \text{ is present in } \Phi] \leq \sum_{T \in \mathcal{T}_0} p^{n_{\text{sink}}(T)}$$
$$\leq p \sum_{T \in \mathcal{T}_0} p^{cn_{\text{edge}}(T)} = p \sum_{n=0}^{\infty} N_n^{\text{edge}} p^{cn} \leq p \sum_{n=0}^{\infty} R^n p^{cn}.$$

・ 同 ト ・ ヨ ト ・ ヨ ト …

We can think of the continuous-time model as the $\varepsilon \to 0$ limit of a discrete-time model that applies three maps:

$$\begin{array}{ll} \varphi^{\rm NEC} & \mbox{with probability } \varepsilon, \\ \varphi^0 & \mbox{with probability } \varepsilon p, \\ \varphi^{\rm id} & \mbox{with the remaining probability,} \end{array}$$

where $\varphi^{id}(x) := x(0)$ is the *identity map*.

Gray (1999) has shown that combining the identity map with an eroder can spoil stability. Let:

$$\varphi(x) := \begin{cases} 0 & \text{if } x(-2,0) = x(-1,0) = 0, \\ 1 & \text{if } x(-3,k) = x(-2,k) = 1 \ \forall |k| \le n, \\ x(0,0) & \text{in all other cases.} \end{cases}$$
